## NeoColab\_REC\_CS23221\_Python Programming

REC\_Python\_Week 4\_CY

Attempt : 1 Total Mark : 40 Marks Obtained : 40

Section 1: Coding

#### 1. Problem Statement

Arjun is working on a mathematical tool to manipulate lists of numbers. He needs a program that reads a list of integers and generates two lists: one containing the squares of the input numbers, and another containing the cubes. Arjun wants to use lambda functions for both tasks.

Write a program that computes the square and cube of each number in the input list using lambda functions.

## **Input Format**

The input consists of a single line of space-separated integers representing the list of input numbers.

Output Format

The first line contains a list of the squared values of the input numbers.

The second line contains a list of the cubed values of the input numbers.

Refer to the sample output for the formatting specifications.

### Sample Test Case

Input: 1 2 3 Output: [1, 4, 9] [1, 8, 27]

#### Answer

# You are using Python
numbers=list(map(int,input().split()))
squares=list(map(lambda x:x\*\*2,numbers))
cubes=list(map(lambda x:x\*x\*x,numbers))
print(squares)
print(cubes)

Status: Correct Marks: 10/10

### 2. Problem Statement

Imagine you are tasked with developing a function for calculating the total cost of an item after applying a sales tax. The sales tax rate is equal to 0.08 and it is defined as a global variable.

The function should accept the cost of the item as a parameter, calculate the tax amount, and return the total cost.

Additionally, the program should display the item cost, sales tax rate, and total cost to the user.

Function Signature: total\_cost(item\_cost)

Input Format

The input consists of a single line containing a positive floating-point number representing the cost of the item.

## Output Format

The output consists of three lines:

"Item Cost:" followed by the cost of the item formatted to two decimal places.

"Sales Tax Rate:" followed by the sales tax rate in percentage.

"Total Cost:" followed by the calculated total cost after applying the sales tax, formatted to two decimal places.

Refer to the sample output for formatting specifications.

### Sample Test Case

Input: 50.00

Output: Item Cost: \$50.00 Sales Tax Rate: 8.0% Total Cost: \$54.00

#### Answer

#

# You are using Python
SALES\_TAX\_RATE=0.08
item\_cost=float(input())
def total\_cost(item\_cost):
 tax=item\_cost\*SALES\_TAX\_RATE
 return item\_cost+tax

total\_cost = total\_cost(item\_cost)
print(f"Item Cost: \${item\_cost:.2f}")
print(f"Sales Tax Rate: {SALES\_TAX\_RATE \* 100}%")
print(f"Total Cost: \${total\_cost:.2f}")

Status: Correct Marks: 10/10

## 3. Problem Statement

Amrita is developing a password strength checker for her website. She wants the checker to consider the length and the diversity of characters used in the password. A strong password should be long and include a mix of character types: uppercase, lowercase, digits, and special symbols.

She also wants the feedback to be user-friendly, so she wants to include the actual password in the output. Help Amrita finish this password checker using Python's built-in string methods.

**Character Types Considered:** 

Lowercase letters (a-z)Uppercase letters (A-Z)Digits (0-9)Special characters (from string.punctuation, e.g. @, !, #, \$)

## **Input Format**

The input consists of a single string representing the user's password.

### **Output Format**

The program prints the strength of the password in this format:

If the password length < 6 characters or fewer than 2 of the 4 character types, the output prints "<password> is Weak"

If password length ≥ 6 and at least 2 different character types, the output prints "<password> is Moderate"

If Password length ≥ 10 and all 4 character types present, the output prints "<password> is Strong"

Refer to the sample output for formatting specifications.

## Sample Test Case

Input: password123

Output: password123 is Moderate

#### Answer

# You are using Python

```
import string
password=input()
has_lower=any(c.islower() for c in password)
has_upper=any(c.isupper() for c in password)
has_digit=any(c.isdigit() for c in password)
has_special=any(c in string.punctuation for c in password)
types_count=sum([has_lower,has_upper,has_digit,has_special])
length=len(password)
if length<6 or types_count<2:
    print(f"{password} is weak")
elif length>=6 and types_count >=2 and (length<=10 or types_count<4):
    print(f"{password} is Moderate")
elif length >=6 and types_count ==4:
    print(f"{password} is strong")
```

Status: Correct Marks: 10/10

#### 4. Problem Statement

Create a program for a mathematics competition where participants need to find the smallest positive divisor of a given integer n. Your program should efficiently determine this divisor using the min() function and display the result.

## **Input Format**

The input consists of a single positive integer n, representing the number for which the smallest positive divisor needs to be found.

## **Output Format**

The output prints the smallest positive divisor of the input integer in the format: "The smallest positive divisor of [n] is: [smallest divisor]".

Refer to the sample output for the exact format.

Sample Test Case

Input: 24

240701371 Output: The smallest positive divisor of 24 is: 2 Answer # You are using Python n=int(input()) divisors=[i for i in range(2,n+1) if n%i == 0] smallest\_divisor=min(divisors) print(f"The smallest positive divisor of {n} is : {smallest\_divisor}") Marks: 10/10 Status: Correct 240701371
